Assignment 2b

The slice plot shows that the best MAE values are concentrated at high subsample about 0.42–0.43 and high colsample_bytree about 0.41–0.43, and at low min_child_samples about 20–25. Low values of both sampling ratios give clearly worse and more scattered MAE, and so do large values of min_child_samples. Because the best points pile up against the edges of the current ranges, I would shift the next search toward those regions and extend past the edges: subsample to about [0.3, 0.8], colsample_bytree to about [0.35, 0.8], and min_child_samples to about [5, 40]. This drops the clearly poor regions and also tests whether the optimum lies just beyond the old boundaries.
